

OVARY

FUNCTIONAL UNITY OF A FOLLICLE

- Oocyte surrounded by granulosa and theca cell
- Normal physiology
- LH → theca cells → granulosa cells → Oocyte
-

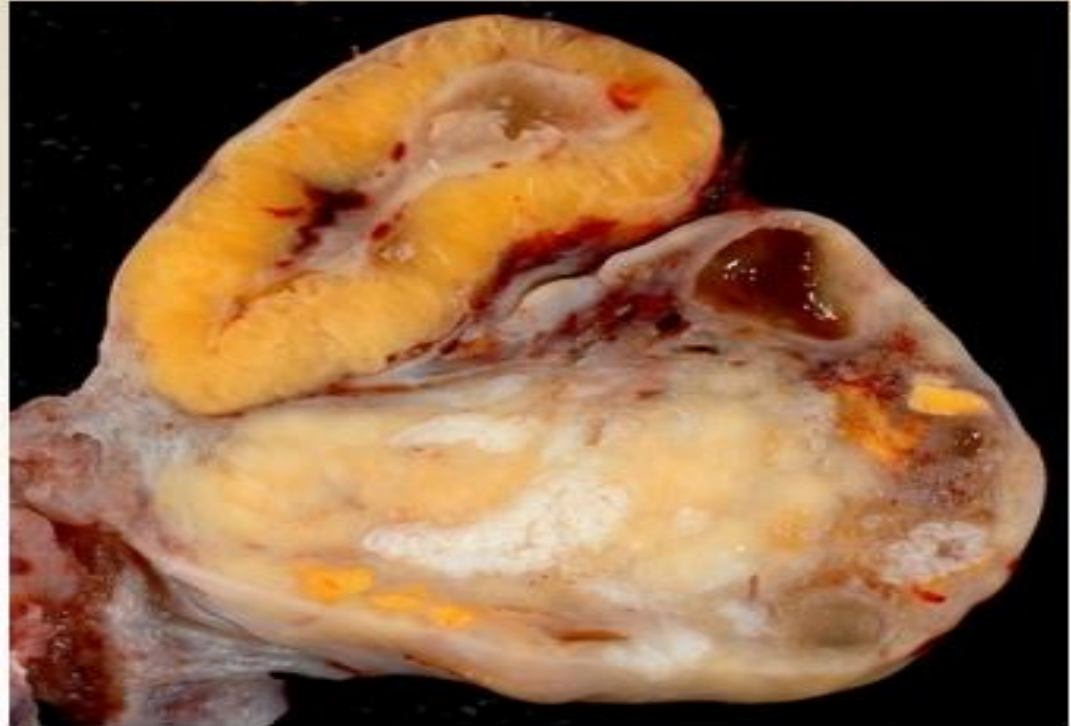

AFTER OVULATION, RESIDUAL FOLLICLE BECOMES CORPUS LUTEUM

- Primarily secretes progesterone
- Prepares endometrium for maintenance of possible pregnancy
- Haemorrhage into corpus luteum can result in haemorrhagic luteal cyst

Corpus Luteum

- After a follicle ovulates, a transient endocrine structure forms.
- **corpus luteum (CL)**
- [plural = corpora lutea]
- The CL produces progesterone.

Human Ovary, by euthman

DEGENERATION OF FOLLICLE

- Results in follicular cyst

PCOD (polycystic ovarian disease)

- Multiple follicular cysts in ovary due to hormone imbalance
- Characterized by increased LH and low FSH hormones

CLASSIC PRESENTATION

- Obese young woman with infertility, oligomenorrhea and hirsutism
- Some patients have insulin resistance
- High circulating estrone levels increases risk for endometrial carcinoma
